Package: LTFHPlus (via r-universe)

September 8, 2024

Type Package

Title Implementation of LT-FH++

Version 2.1.1.9000

Description Implementation of LT-FH++, an extension of the liability
threshold family history (LT-FH) model. LT-FH++ uses a Gibbs
sampler for sampling from the truncated multivariate normal
distribution and allows for flexible family structures. LT-FH++
was first described in Pedersen, Emil M., et al. (2022)
<https://pure.au.dk/ws/portalfiles/portal/353346245/> as an
extension to LT-FH with more flexible family structures, and
again as the age-dependent liability threshold (ADuLT) model
Pedersen, Emil M., et al. (2023)
<https://www.nature.com/articles/s41467-023-41210-z> as an
alternative to traditional time-to-event genome-wide
association studies, where family history was not considered.

construct_covmat *Constructing a covariance matrix for a variable number of phenotypes*

Description

construct_covmat returns the covariance matrix for an underlying target individual and a variable number of its family members for a variable number of phenotypes. It is a wrapper around construct_covmat_single and construct_covmat_multi.

Usage

```
construct_covmat(
  fam_vec = c("m", "f", "s1", "mgm", "mgf", "pgm", "pgf"),
  n_fam = NULL,
  add_ind = TRUE,
  h2 = 0.5,
  genetic_corrmat = NULL,
```

```
    full_corrmat = NULL,
    phen_names = NULL
)
```

Arguments

fam_vec	A vector of strings holding the different family members. All family members must be represented by strings from the following list:

- m (Mother)
- f (Father)
- c[0-9]*.[0-9]* (Children)
- mgm (Maternal grandmother)
- mgf (Maternal grandfather)
- pgm (Paternal grandmother)
- pgf (Paternal grandfather)
- s[0-9]* (Full siblings)
- mhs[0-9]* (Half-siblings - maternal side)
- phs[0-9]* (Half-siblings - paternal side)
- mau[0-9]* (Aunts/Uncles - maternal side)
- pau[0-9]* (Aunts/Uncles - paternal side). Defaults to c("m","f","s1","mgm","mgf","pgm","pgf").

n_fam	A named vector holding the desired number of family members. See [setNames](). All names must be picked from the list mentioned above. Defaults to NULL.
add_ind	A logical scalar indicating whether the genetic component of the full liability as well as the full liability for the underlying individual should be included in the covariance matrix. Defaults to TRUE.
h2	Either a number representing the heritability on liability scale for one single phenotype or a numeric vector representing the liability-scale heritabilities for a positive number of phenotypes. All entries in h2 must be non-negative and at most 1.
genetic_corrmat	
	Either NULL or a numeric matrix holding the genetic correlations between the desired phenotypes. All diagonal entries must be equal to one, while all off-diagonal entries must be between -1 and 1. In addition, the matrix must be symmetric. Defaults to NULL.
full_corrmat	Either NULL or a numeric matrix holding the full correlations between the desired phenotypes. All diagonal entries must be equal to one, while all off-diagonal entries must be between -1 and 1. In addition, the matrix must be symmetric. Defaults to NULL.
phen_names	Either NULL or a character vector holding the phenotype names. These names will be used to create the row and column names for the covariance matrix. If it is not specified, the names will default to phenotype1, phenotype2, etc. Defaults to NULL.

Details

This function can be used to construct a covariance matrix for a given number of family members. If h2 is a number, each entry in this covariance matrix equals the percentage of shared DNA between the corresponding individuals times the liability-scale heritability

$$h^2$$

. However, if h2 is a numeric vector, and genetic_corrmat and full_corrmat are two symmetric correlation matrices, each entry equals either the percentage of shared DNA between the corresponding individuals times the liability-scale heritability

$$h^2$$

or the percentage of shared DNA between the corresponding individuals times the correlation between the corresponding phenotypes. The family members can be specified using one of two possible formats.

Value

If either fam_vec or n_fam is used as the argument, if it is of the required format, if add_ind is a logical scalar and h2 is a number satisfying

$$0 \leq h2 \leq 1$$

, then the function construct_covmat will return a named covariance matrix, which row- and column-number corresponds to the length of fam_vec or n_fam (+ 2 if add_ind=TRUE). However, if h2 is a numeric vector satisfying

$$0 \leq h2_i \leq 1$$

for all

$$i \in \{1, ..., n_pheno\}$$

and if genetic_corrmat and full_corrmat are two numeric and symmetric matrices satisfying that all diagonal entries are one and that all off-diagonal entries are between -1 and 1, then construct_covmat will return a named covariance matrix, which number of rows and columns corresponds to the number of phenotypes times the length of fam_vec or n_fam (+ 2 if add_ind=TRUE). If both fam_vec and n_fam are equal to c() or NULL, the function returns either a 2×2 matrix holding only the correlation between the genetic component of the full liability and the full liability for the individual under consideration, or a

$$(2 \times n_pheno) \times (2 \times n_pheno)$$

matrix holding the correlation between the genetic component of the full liability and the full liability for the underlying individual for all phenotypes. If both fam_vec and n_fam are specified, the user is asked to decide on which of the two vectors to use. Note that the returned object has different attributes, such as fam_vec, n_fam, add_ind and h2.

Examples

```
construct_covmat()
construct_covmat(fam_vec = c("m","mgm","mgf","mhs1","mhs2","mau1"),
                 n_fam = NULL,
                 add_ind = TRUE,
                 h2 = 0.5)
construct_covmat(fam_vec = NULL,
                 n_fam = stats::setNames(c(1,1,1,2,2), c("m","mgm","mgf","s","mhs")),
                 add_ind = FALSE,
                 h2 = 0.3)
construct_covmat(h2 = c(0.5,0.5), genetic_corrmat = matrix(c(1,0.4,0.4,1), nrow = 2),
                 full_corrmat = matrix(c(1,0.6,0.6,1), nrow = 2))
```

---

construct_covmat_multi

Constructing a covariance matrix for multiple phenotypes

Description

construct_covmat_multi returns the covariance matrix for an underlying target individual and a variable number of its family members for multiple phenotypes.

Usage

```
construct_covmat_multi(
  fam_vec = c("m", "f", "s1", "mgm", "mgf", "pgm", "pgf"),
  n_fam = NULL,
  add_ind = TRUE,
  genetic_corrmat,
  full_corrmat,
  h2_vec,
  phen_names = NULL
)
```

Arguments

fam_vec   A vector of strings holding the different family members. All family members
                 must be represented by strings from the following list:

- m (Mother)
- f (Father)
- c[0-9]*.[0-9]* (Children)
- mgm (Maternal grandmother)
- mgf (Maternal grandfather)
- pgm (Paternal grandmother)
- pgf (Paternal grandfather)

- s[0-9]* (Full siblings)
- mhs[0-9]* (Half-siblings - maternal side)
- phs[0-9]* (Half-siblings - paternal side)
- mau[0-9]* (Aunts/Uncles - maternal side)
- pau[0-9]* (Aunts/Uncles - paternal side). Defaults to c("m","f","s1","mgm","mgf","pgm","pgf").

n_fam	A named vector holding the desired number of family members. See [setNames](). All names must be picked from the list mentioned above. Defaults to NULL.
add_ind	A logical scalar indicating whether the genetic component of the full liability as well as the full liability for the underlying individual should be included in the covariance matrix. Defaults to TRUE.
genetic_corrmat	
	A numeric matrix holding the genetic correlations between the desired phenotypes. All diagonal entries must be equal to one, while all off-diagonal entries must be between -1 and 1. In addition, the matrix must be symmetric.
full_corrmat	A numeric matrix holding the full correlations between the desired phenotypes. All diagonal entries must be equal to one, while all off-diagonal entries must be between -1 and 1. In addition, the matrix must be symmetric.
h2_vec	A numeric vector representing the liability-scale heritabilities for all phenotypes. All entries in h2_vec must be non-negative and at most 1.
phen_names	A character vector holding the phenotype names. These names will be used to create the row and column names for the covariance matrix. If it is not specified, the names will default to phenotype1, phenotype2, etc. Defaults to NULL.

Details

This function can be used to construct a covariance matrix for a given number of family members. Each entry in this covariance matrix equals either the percentage of shared DNA between the corresponding individuals times the liability-scale heritability h^2 or the percentage of shared DNA between the corresponding individuals times the correlation between the corresponding phenotypes. That is, for the same phenotype, the covariance between all combinations of the genetic component of the full liability and the full liability is given by

$$\text{Cov}\left(l_g, l_g\right) = h^2,$$

$$\text{Cov}\left(l_g, l_o\right) = h^2,$$

$$\text{Cov}\left(l_o, l_g\right) = h^2$$

and

$$\text{Cov}\left(l_o, l_o\right) = 1.$$

For two different phenotypes, the covariance is given by

$$\text{Cov}\left(l_g^1, l_g^2\right) = \rho_g^{1,2},$$

$$\text{Cov}\left(l_g^1, l_o^2\right) = \rho_g^{1,2},$$

$$\text{Cov}\left(l_o^1, l_g^2\right) = \rho_g^{1,2}$$

and

$$\text{Cov}\left(l_o^1, l_o^2\right) = \rho_g^{1,2} + \rho_e^{1,2},$$

where l_g^i and l_o^i are the genetic component of the full liability and the full liability for phenotype i, respectively, $\rho_g^{i,j}$ is the genetic correlation between phenotype i and j and $\rho_e^{1,2}$ is the environmental correlation between phenotype i and j. The family members can be specified using one of two possible formats.

Value

If either `fam_vec` or `n_fam` is used as the argument and if it is of the required format, if `genetic_corrmat` and `full_corrmat` are two numeric and symmetric matrices satisfying that all diagonal entries are one and that all off-diagonal entries are between -1 and 1, and if `h2_vec` is a numeric vector satisfying $0 \leq h2_i \leq 1$ for all $i \in \{1, ..., n_pheno\}$, then the output will be a named covariance matrix. The number of rows and columns corresponds to the number of phenotypes times the length of `fam_vec` or `n_fam` (+ 2 if add_ind=TRUE). If both `fam_vec` and `n_fam` are equal to `c()` or `NULL`, the function returns a $(2 \times n_pheno) \times (2 \times n_pheno)$ matrix holding only the correlation between the genetic component of the full liability and the full liability for the underlying individual for all phenotypes. If both `fam_vec` and `n_fam` are specified, the user is asked to decide on which of the two vectors to use. Note that the returned object has a number different attributes,namely `fam_vec`, `n_fam`, `add_ind`, `genetic_corrmat`, `full_corrmat`, `h2` and `phenotype_names`.

Examples

```
construct_covmat_multi(fam_vec = NULL,
                       genetic_corrmat = matrix(c(1, 0.5, 0.5, 1), nrow = 2),
                       full_corrmat = matrix(c(1, 0.55, 0.55, 1), nrow = 2),
                       h2_vec = c(0.37,0.44),
                       phen_names = c("p1","p2"))
construct_covmat_multi(fam_vec = c("m","mgm","mgf","mhs1","mhs2","mau1"),
                       n_fam = NULL,
                       add_ind = TRUE,
                       genetic_corrmat = diag(3),
                       full_corrmat = diag(3),
                       h2_vec = c(0.8, 0.65))
construct_covmat_multi(fam_vec = NULL,
                   n_fam = stats::setNames(c(1,1,1,2,2), c("m","mgm","mgf","s","mhs")),
                       add_ind = FALSE,
                       genetic_corrmat = diag(2),
                       full_corrmat = diag(2),
                       h2_vec = c(0.75,0.85))
```

---

construct_covmat_single

Constructing a covariance matrix for a single phenotype

Description

construct_covmatc_single returns the covariance matrix for an underlying target individual and a variable number of its family members

Usage

```
construct_covmat_single(
  fam_vec = c("m", "f", "s1", "mgm", "mgf", "pgm", "pgf"),
  n_fam = NULL,
  add_ind = TRUE,
  h2 = 0.5
)
```

Arguments

fam_vec   A vector of strings holding the different family members. All family members must be represented by strings from the following list:

- m (Mother)
- f (Father)
- c[0-9]*.[0-9]* (Children)
- mgm (Maternal grandmother)
- mgf (Maternal grandfather)
- pgm (Paternal grandmother)
- pgf (Paternal grandfather)
- s[0-9]* (Full siblings)
- mhs[0-9]* (Half-siblings - maternal side)
- phs[0-9]* (Half-siblings - paternal side)
- mau[0-9]* (Aunts/Uncles - maternal side)
- pau[0-9]* (Aunts/Uncles - paternal side).

n_fam   A named vector holding the desired number of family members. See [setNames](#). All names must be picked from the list mentioned above. Defaults to NULL.

add_ind   A logical scalar indicating whether the genetic component of the full liability as well as the full liability for the underlying individual should be included in the covariance matrix. Defaults to TRUE.

h2   A number representing the squared heritability on liability scale for a single phenotype. Must be non-negative and at most 1. Defaults to 0.5.

Details

This function can be used to construct a covariance matrix for a given number of family members. Each entry in this covariance matrix equals the percentage of shared DNA between the corresponding individuals times the liability-scale heritability h^2. The family members can be specified using one of two possible formats.

Value

If either `fam_vec` or `n_fam` is used as the argument, if it is of the required format and `h2` is a number satisfying $0 \leq h2 \leq 1$, then the output will be a named covariance matrix. The number of rows and columns corresponds to the length of `fam_vec` or `n_fam` (+ 2 if add_ind=TRUE). If both `fam_vec = c()/NULL` and `n_fam = c()/NULL`, the function returns a 2×2 matrix holding only the correlation between the genetic component of the full liability and the full liability for the individual. If both `fam_vec` and `n_fam` are given, the user is asked to decide on which of the two vectors to use. Note that the returned object has different attributes, such as `fam_vec`, `n_fam`, `add_ind` and `h2`.

```
construct_covmat_single()
construct_covmat_single(fam_vec = c("m","mgm","mgf","mhs1","mhs2","mau1"),
n_fam = NULL, add_ind = TRUE, h2 = 0.5)
construct_covmat_single(fam_vec = NULL, n_fam = stats::setNames(c(1,1,1,2,2),
c("m","mgm","mgf","s","mhs")), add_ind = FALSE, h2 = 0.3)
```

---

convert_age_to_cir   *Convert age to cumulative incidence rate*

Description

`convert_age_to_cir` computes the cumulative incidence rate from a person's age.

Usage

```
convert_age_to_cir(age, pop_prev = 0.1, mid_point = 60, slope = 1/8)
```

Arguments

age	A non-negative number representing the individual's age.
pop_prev	A positive number representing the overall population prevalence. Must be at most 1. Defaults to 0.1.
mid_point	A positive number representing the mid point logistic function. Defaults to 60.
slope	A number holding the rate of increase. Defaults to 1/8.

Details

Given a person's age, `convert_age_to_cir` can be used to compute the cumulative incidence rate (cir), which is given by the formula

$$pop\_prev/(1 + exp((mid\_point - age) * slope))$$

Value

If age and mid_point are positive numbers, if pop_prev is a positive number between 0 and 1 and if slope is a valid number, then `convert_age_to_cir` returns a number, which is equal to the cumulative incidence rate.

Examples

```
curve(sapply(age, convert_age_to_cir), from = 10, to = 110, xname = "age")
```

`convert_age_to_thresh`   *Convert age to threshold*

Description

`convert_age_to_thresh` computes the threshold from a person's age using either the logistic function or the truncated normal distribution

Usage

```
convert_age_to_thresh(
  age,
  dist = "logistic",
  pop_prev = 0.1,
  mid_point = 60,
  slope = 1/8,
  min_age = 10,
  max_age = 90,
  lower = stats::qnorm(0.05, lower.tail = FALSE),
  upper = Inf
)
```

Arguments

age	A non-negative number representing the individual's age.
dist	A string indicating which distribution to use. If dist = "logistic", the logistic function will be used to compute the age of onset. If dist = "normal", the truncated normal distribution will be used instead. Defaults to "logistic".
pop_prev	Only necessary if dist = "logistic". A positive number representing the overall population prevalence. Must be at most 1. Defaults to 0.1.

mid_point	Only necessary if dist = "logistic". A positive number representing the mid point logistic function. Defaults to 60.
slope	Only necessary if dist = "logistic". A number holding the rate of increase. Defaults to 1/8.
min_age	Only necessary if dist = "normal". A positive number representing the individual's earliest age. Defaults to 10.
max_age	Only necessary if dist = "normal". A positive number representing the individual's latest age. Must be greater than min_aoo. Defaults to 90.
lower	Only necessary if dist = "normal". A number representing the lower cutoff point for the truncated normal distribution. Defaults to 1.645 (stats::qnorm(0.05, lower.tail = FALSE)).
upper	Only necessary if dist = "normal". A number representing the upper cutoff point of the truncated normal distribution. Must be greater or equal to lower. Defaults to Inf.

Details

Given a person's age, `convert_age_to_thresh` can be used to first compute the cumulative incidence rate (cir), which is then used to compute the threshold using either the logistic function or the truncated normal distribution. Under the logistic function, the formula used to compute the threshold from an individual's age is given by

$$qnorm(pop\_prev/(1 + exp((mid\_point - age) * slope)), lower.tail = F)$$

, while it is given by

$$qnorm((1 - (age - min\_age)/max\_age) * (pnorm(upper) - pnorm(lower)) + pnorm(lower))$$

under the truncated normal distribution.

Value

If age is a positive number and all other necessary arguments are valid, then `convert_age_to_thresh` returns a number, which is equal to the threshold.

Examples

```
curve(sapply(age, convert_age_to_thresh), from = 10, to = 110, xname = "age")
```

---

convert_cir_to_age	*Convert cumulative incidence rate to age*

Description

`convert_cir_to_age` computes the age from a person's cumulative incidence rate.

Usage

```
convert_cir_to_age(cir, pop_prev = 0.1, mid_point = 60, slope = 1/8)
```

Arguments

`cir`	A positive number representing the individual's cumulative incidence rate.
`pop_prev`	A positive number representing the overall population prevalence. Must be at most 1 and must be larger than cir. Defaults to 0.1.
`mid_point`	A positive number representing the mid point logistic function. Defaults to 60.
`slope`	A number holding the rate of increase. Defaults to 1/8.

Details

Given a person's cumulative incidence rate (cir), `convert_cir_to_age` can be used to compute the corresponding age, which is given by

$$mid\_point - \log(pop\_prev/cir - 1) * 1/slope$$

Value

If cir and mid_point are positive numbers, if pop_prev is a positive number between 0 and 1 and if slope is a valid number, then `convert_cir_to_age` returns a number, which is equal to the current age.

Examples

```
curve(sapply(cir, convert_cir_to_age), from = 0.001, to = 0.099, xname = "cir")
```

`convert_format`	*Attempts to convert the list entry input format to a long format*

Description

Attempts to convert the list entry input format to a long format

Usage

```
convert_format(family, threshs, personal_id_col = "pid", role_col = NULL)
```

Arguments

`family`	a tibble with two entries, family id and personal id. personal id should end in "_role", if a role column is not present.
`threshs`	thresholds, with a personal id (without role) as well as the lower and upper thresholds
`personal_id_col`	
	column name that holds the personal id
`role_col`	column name that holds the role

Value

returns a format similar to `prepare_LTFHPlus_input`, which is used by `estimate_liability`

Examples

```
family <- data.frame(
fam_id = c(1, 1, 1, 1),
pid = c(1, 2, 3, 4),
role = c("o", "m", "f", "pgf")
)

threshs <- data.frame(
  pid = c(1, 2, 3, 4),
  lower = c(-Inf, -Inf, 0.8, 0.7),
  upper = c(0.8, 0.8, 0.8, 0.7)
)

convert_format(family, threshs)
```

`convert_liability_to_aoo`

Convert liability to age of onset

Description

`convert_liability_to_aoo` computes the age of onset from an individual's true underlying liability using either the logistic function or the truncated normal distribution.

Usage

```
convert_liability_to_aoo(
  liability,
  dist = "logistic",
  pop_prev = 0.1,
  mid_point = 60,
  slope = 1/8,
  min_aoo = 10,
  max_aoo = 90,
  lower = stats::qnorm(0.05, lower.tail = FALSE),
  upper = Inf
)
```

Arguments

liability   A number representing the individual's true underlying liability.

dist	A string indicating which distribution to use. If dist = "logistic", the logistic function will be used to compute the age of onset. If dist = "normal", the truncated normal distribution will be used instead. Defaults to "logistic".
pop_prev	Only necessary if dist = "logistic". A positive number representing the overall population prevalence. Must be at most 1. Defaults to 0.1.
mid_point	Only necessary if dist = "logistic". A positive number representing the mid point logistic function. Defaults to 60.
slope	Only necessary if dist = "logistic". A number holding the rate of increase. Defaults to 1/8.
min_aoo	Only necessary if dist = "normal". A positive number representing the individual's earliest age of onset. Defaults to 10.
max_aoo	Only necessary if dist = "normal". A positive number representing the individual's latest age of onset. Must be greater than min_aoo. Defaults to 90.
lower	Only necessary if dist = "normal". A number representing the lower cutoff point for the truncated normal distribution. Defaults to 1.645 (stats::qnorm(0.05, lower.tail = FALSE)).
upper	Only necessary if dist = "normal". A number representing the upper cutoff point of the truncated normal distribution. Must be greater or equal to lower. Defaults to Inf.

Details

Given a person's cumulative incidence rate (cir), `convert_liability_to_aoo` can be used to compute the corresponding age. Under the logistic function, the age is given by

$$mid\_point - log(pop\_prev/cir - 1) * 1/slope$$

, while it is given by

$$(1 - truncated\_normal\_cdf(liability = liability, lower = lower, upper = upper)) * max\_aoo + min\_aoo$$

under the truncated normal distribution.

Value

If liability is a number and all other necessary arguments are valid, then `convert_liability_to_aoo` returns a positive number, which is equal to the age of onset.

Examples

```
curve(sapply(liability, convert_liability_to_aoo), from = 1.3, to = 3.5, xname = "liability")
curve(sapply(liability, convert_liability_to_aoo, dist = "normal"),
 from = qnorm(0.05, lower.tail = FALSE), to = 3.5, xname = "liability")
```

convert_observed_to_liability_scale

Convert the heritability on the observed scale to that on the liability scale

Description

`convert_observed_to_liability_scale` transforms the heritability on the observed scale to the heritability on the liability scale.

Usage

```
convert_observed_to_liability_scale(
  obs_h2 = 0.5,
  pop_prev = 0.05,
  prop_cases = 0.5
)
```

Arguments

`obs_h2`	A number or numeric vector representing the liability-scale heritability(ies)on the observed scale. Must be non-negative and at most 1. Defaults to 0.5
`pop_prev`	A number or numeric vector representing the population prevalence(s). All entries must be non-negative and at most one. If it is a vector, it must have the same length as obs_h2. Defaults to 0.05.
`prop_cases`	Either NULL or a number or a numeric vector representing the proportion of cases in the sample. All entries must be non-negative and at most one. If it is a vector, it must have the same length as obs_h2. Defaults to 0.5.

Details

This function can be used to transform the heritability on the observed scale to that on the liability scale. `convert_observed_to_liability_scale` uses either Equation 17 (if prop_cases = NULL) or Equation 23 from Sang Hong Lee, Naomi R. Wray, Michael E. Goddard and Peter M. Visscher, "Estimating Missing Heritability for Diseases from Genome-wide Association Studies", The American Journal of Human Genetics, Volume 88, Issue 3, 2011, pp. 294-305, doi:10.1016/j.ajhg.2011.02.002 to transform the heritability on the observed scale to the heritability on the liability scale.

Value

If `obs_h2`, `pop_prev` and `prop_cases` are non-negative numbers that are at most one, the function returns the heritability on the liability scale using Equation 23 from Sang Hong Lee, Naomi R. Wray, Michael E. Goddard and Peter M. Visscher, "Estimating Missing Heritability for Diseases from Genome-wide Association Studies", The American Journal of Human Genetics, Volume 88, Issue 3, 2011, pp. 294-305, doi:10.1016/j.ajhg.2011.02.002. If obs_h2, pop_prev and

prop_cases are non-negative numeric vectors where all entries are at most one, the function returns a vector of the same length as obs_h2. Each entry holds to the heritability on the liability scale which was obtained from the corresponding entry in obs_h2 using Equation 23. If obs_h2 and pop_prev are non-negative numbers that are at most one and prop_cases is NULL, the function returns the heritability on the liability scale using Equation 17 from Sang Hong Lee, Naomi R. Wray, Michael E. Goddard and Peter M. Visscher, "Estimating Missing Heritability for Diseases from Genome-wide Association Studies", The American Journal of Human Genetics, Volume 88, Issue 3, 2011, pp. 294-305, doi:10.1016/j.ajhg.2011.02.002. If obs_h2 and pop_prev are non-negative numeric vectors such that all entries are at most one, while prop_cases is NULL, convert_observed_to_liability_scale returns a vector of the same length as obq_h2. Each entry holds to the liability-scale heritability that was obtained from the corresponding entry in obs_h2 using Equation 17.

Examples

```
convert_observed_to_liability_scale()
convert_observed_to_liability_scale(prop_cases=NULL)
convert_observed_to_liability_scale(obs_h2 = 0.8, pop_prev = 1/44,
                                    prop_cases = NULL)
convert_observed_to_liability_scale(obs_h2 = c(0.5,0.8),
                                    pop_prev = c(0.05, 1/44),
                                    prop_cases = NULL)
```

---

correct_positive_definite

Positive definite matrices

Description

correct_positive_definite verifies that a given covariance matrix is indeed positive definite by checking that all eigenvalues are positive. If the given covariance matrix is not positive definite, correct_positive_definite tries to modify the underlying correlation matrices genetic_corrmat and full_corrmat in order to obtain a positive definite covariance matrix.

Usage

```
correct_positive_definite(
  covmat,
  correction_val = 0.99,
  correction_limit = 100
)
```

Arguments

covmat   A symmetric and numeric matrix. If the covariance matrix should be corrected, it must have a number of attributes, such as `attr(covmat,"fam_vec")`, `attr(covmat,"n_fam")`, `attr(covmat,"add_ind")`, `attr(covmat,"h2")`, `attr(covmat,"genetic_corrmat")`, `attr(covmat,"full_corrmat")` and `attr(covmat,"phenotype_names")`. Any covariance matrix obtained by `construct_covmat`, `construct_covmat_single` or `construct_covmat_multi` will have these attributes by default.

correction_val A positive number representing the amount by which `genetic_corrmat` and `full_corrmat` will be changed, if some eigenvalues are non-positive. That is, correction_val is the number that will be multiplied to all off_diagonal entries in `genetic_corrmat` and `full_corrmat`. Defaults to 0.99.

correction_limit

A positive integer representing the upper limit for the correction procedure. Defaults to 100.

Details

This function can be used to verify that a given covariance matrix is positive definite. It calculates all eigenvalues in order to investigate whether they are all positive. This property is necessary for the covariance matrix to be used as a Gaussian covariance matrix. It is especially useful to check whether any covariance matrix obtained by `construct_covmat_multi` is positive definite. If the given covariance matrix is not positive definite, correct_positive_definite tries to modify the underlying correlation matrices (called `genetic_corrmat` and `full_corrmat` in `construct_covmat` or `construct_covmat_multi`) by multiplying all off-diagonal entries in the correlation matrices by a given number.

Value

If covmat is a symmetric and numeric matrix and all eigenvalues are positive, `correct_positive_definite` simply returns covmat. If some eigenvalues are not positive and correction_val is a positive number, `correct_positive_definite` tries to convert covmat into a positive definite matrix. If covmat has attributes add_ind, h2, genetic_corrmat, full_corrmat and phenotype_names, correct_positive_definite computes a new covariance matrix using slightly modified correlation matrices genetic_corrmat and full_corrmat. If the correction is performed successfully, i.e. if the new covariance matrix is positive definite,the new covariance matrix is returned. Otherwise, correct_positive_definite returns the original covariance matrix.

See Also

`construct_covmat`, `construct_covmat_single` and `construct_covmat_multi`.

Examples

```
ntrait <- 2
genetic_corrmat <- matrix(0.6, ncol = ntrait, nrow = ntrait)
diag(genetic_corrmat) <- 1
full_corrmat <- matrix(-0.25, ncol = ntrait, nrow = ntrait)
diag(full_corrmat) <- 1
h2_vec <- rep(0.6, ntrait)
```

```
cov <- construct_covmat(fam_vec = c("m", "f"),
  genetic_corrmat = genetic_corrmat,
  h2 = h2_vec,
  full_corrmat = full_corrmat)
cov
correct_positive_definite(cov)
```

---

estimate_gen_liability_ltfh

Estimate genetic liability similar to LT-FH

Description

Estimate genetic liability similar to LT-FH

Usage

```
estimate_gen_liability_ltfh(
  h2,
  phen,
  child_threshold,
  parent_threshold,
  status_col_offspring = "CHILD_STATUS",
  status_col_father = "P1_STATUS",
  status_col_mother = "P2_STATUS",
  status_col_siblings = "SIB_STATUS",
  number_of_siblings_col = "NUM_SIBS",
  tol = 0.01
)
```

Arguments

h2	Liability scale heritability of the trait being analysed.
phen	tibble or data.frame with status of the genotyped individual, parents and siblings.
child_threshold	
	single numeric value that is used as threshold for the offspring and siblings.
parent_threshold	
	single numeric value that is used as threshold for both parents
status_col_offspring	
	Column name of status for the offspring
status_col_father	
	Column name of status for the father
status_col_mother	
	Column name of status for the mother
status_col_siblings	
	Column name of status for the siblings

number_of_siblings_col
>   Column name for the number of siblings for a given individual

tol   Convergence criteria of the Gibbs sampler. Default is 0.01, meaning a standard
>   error of the mean below 0.01

Value

Returns the estimated genetic liabilities.

Examples

```
phen <- data.frame(
CHILD_STATUS = c(0,0),
P1_STATUS = c(1,1),
P2_STATUS = c(0,1),
SIB_STATUS = c(1,0),
NUM_SIBS = c(2,0))

h2 <- 0.5
child_threshold <- 0.7
parent_threshold <- 0.8

estimate_gen_liability_ltfh(h2, phen, child_threshold, parent_threshold)
```

---

estimate_liability   *Estimating the genetic or full liability for a variable number of pheno-*
>   *types*

Description

estimate_liability estimates the genetic component of the full liability and/or the full liability
for a number of individuals based on their family history for one or more phenotypes. It is a wrapper
around estimate_liability_single and estimate_liability_multi.

Usage

```
estimate_liability(
  .tbl = NULL,
  family_graphs = NULL,
  h2 = 0.5,
  pid = "PID",
  fam_id = "fam_ID",
  role = "role",
  family_graphs_col = "fam_graph",
  out = c(1),
  tol = 0.01,
  genetic_corrmat = NULL,
```

```
    full_corrmat = NULL,
    phen_names = NULL
)
```

Arguments

.tbl   A matrix, list or data frame that can be converted into a tibble. Must have at
                     least five columns that hold the family identifier, the personal identifier, the role
                     and the lower and upper thresholds for all phenotypes of interest. Note that the
                     role must be one of the following abbreviations

                        • g (Genetic component of full liability)
                        • o (Full liability)
                        • m (Mother)
                        • f (Father)
                        • c[0-9]*.[0-9]* (Children)
                        • mgm (Maternal grandmother)
                        • mgf (Maternal grandfather)
                        • pgm (Paternal grandmother)
                        • pgf (Paternal grandfather)
                        • s[0-9]* (Full siblings)
                        • mhs[0-9]* (Half-siblings - maternal side)
                        • phs[0-9]* (Half-siblings - paternal side)
                        • mau[0-9]* (Aunts/Uncles - maternal side)
                        • pau[0-9]* (Aunts/Uncles - paternal side). Defaults to NULL.

family_graphs   A tibble with columns pid and family_graph_col. See prepare_graph for con-
                     struction of the graphs. The family graphs Defaults to NULL.

h2   Either a number representing the heritability on liability scale for a single phe-
                     notype, or a numeric vector representing the liability-scale heritabilities for all
                     phenotypes. All entries in h2 must be non-negative and at most 1.

pid   A string holding the name of the column in family and threshs that hold the
                     personal identifier(s). Defaults to "PID".

fam_id   A string holding the name of the column in family that holds the family identi-
                     fier. Defaults to "fam_ID".

role   A string holding the name of the column in .tbl that holds the role.Each role
                     must be chosen from the following list of abbreviations

                        • g (Genetic component of full liability)
                        • o (Full liability)
                        • m (Mother)
                        • f (Father)
                        • c[0-9]*.[0-9]* (Children)
                        • mgm (Maternal grandmother)
                        • mgf (Maternal grandfather)
                        • pgm (Paternal grandmother)

- pgf (Paternal grandfather)
- s[0-9]* (Full siblings)
- mhs[0-9]* (Half-siblings - maternal side)
- phs[0-9]* (Half-siblings - paternal side)
- mau[0-9]* (Aunts/Uncles - maternal side)
- pau[0-9]* (Aunts/Uncles - paternal side). Defaults to "role".

family_graphs_col

    Name of column with family graphs in family_graphs. Defaults to "fam_graph".

out   A character or numeric vector indicating whether the genetic component of the full liability, the full liability or both should be returned. If out = c(1) or out = c("genetic"), the genetic liability is estimated and returned. If out = c(2) or out = c("full"), the full liability is estimated and returned. If out = c(1,2) or out = c("genetic", "full"), both components are estimated and returned. Defaults to c(1).

tol   A number that is used as the convergence criterion for the Gibbs sampler. Equals the standard error of the mean. That is, a tolerance of 0.2 means that the standard error of the mean is below 0.2. Defaults to 0.01.

genetic_corrmat

    Either NULL (if h2 is a number) or a numeric matrix (if h2 is a vector of length > 1) holding the genetic correlations between the desired phenotypes. All diagonal entries must be equal to one, while all off-diagonal entries must be between -1 and 1. In addition, the matrix must be symmetric. Defaults to NULL.

full_corrmat   Either NULL (if h2 is a number) or a numeric matrix (if h2 is a vector of length > 1) holding the full correlations between the desired phenotypes. All diagonal entries must be equal to one, while all off-diagonal entries must be between -1 and 1. In addition, the matrix must be symmetric. Defaults to NULL.

phen_names   Either NULL or a character vector holding the phenotype names. These names will be used to create the row and column names for the covariance matrix. If it is not specified, the names will default to phenotype1, phenotype2, etc. Defaults to NULL.

Details

This function can be used to estimate either the genetic component of the full liability, the full liability or both for a variable number of traits.

Value

If family and threshs are two matrices, lists or data frames that can be converted into tibbles, if family has two columns named like the strings represented in pid and fam_id, if threshs has a column named like the string given in pid as well as a column named "lower" and a column named "upper" and if the liability-scale heritability h2 is a number (length(h2)=1), and out, tol and always_add are of the required form, then the function returns a tibble with either four or six columns (depending on the length of out). The first two columns correspond to the columns fam_id and pid ' present in family. If out is equal to c(1) or c("genetic"), the third and fourth column hold the estimated genetic liability as well as the corresponding standard error, respectively. If out equals c(2) or c("full"), the third and fourth column hold the estimated full liability as well as

the corresponding standard error, respectively. If out is equal to `c(1,2)` or `c("genetic","full")`, the third and fourth column hold the estimated genetic liability as well as the corresponding standard error, respectively, while the fifth and sixth column hold the estimated full liability as well as the corresponding standard error, respectively. If h2 is a numeric vector of length greater than 1 and if `genetic_corrmat`, `full_corrmat`, `out` and `tol` are of the required form, then the function returns a tibble with at least six columns (depending on the length of out). The first two columns correspond to the columns `fam_id` and `pid` present in the tibble `family`. If out is equal to `c(1)` or `c("genetic")`, the third and fourth columns hold the estimated genetic liability as well as the corresponding standard error for the first phenotype, respectively. If out equals `c(2)` or `c("full")`, the third and fourth columns hold the estimated full liability as well as the corresponding standard error for the first phenotype, respectively. If out is equal to `c(1,2)` or `c("genetic","full")`, the third and fourth columns hold the estimated genetic liability as well as the corresponding standard error for the first phenotype, respectively, while the fifth and sixth columns hold the estimated full liability as well as the corresponding standard error for the first phenotype, respectively. The remaining columns hold the estimated genetic liabilities and/or the estimated full liabilities as well as the corresponding standard errors for the remaining phenotypes.

```

---

estimate_liability_multi

Estimating the genetic or full liability for multiple phenotypes

---

Description

`estimate_liability_multi` estimates the genetic component of the full liability and/or the full liability for a number of individuals based on their family history for a variable number of phenotypes.

Usage

```
estimate_liability_multi(
  .tbl = NULL,
  family_graphs = NULL,
  h2_vec,
  genetic_corrmat,
  full_corrmat,
  phen_names = NULL,
  pid = "PID",
  fam_id = "fam_ID",
  role = "role",
  family_graphs_col = "fam_graph",
  out = c(1),
  tol = 0.01
)
```

Arguments

.tbl   A matrix, list or data frame that can be converted into a tibble. Must have at
                        least seven columns that hold the family identifier, the personal identifier, the
                        role and the lower and upper thresholds for all phenotypes of interest. Note that
                        the role must be one of the following abbreviations

- g (Genetic component of full liability)
- o (Full liability)
- m (Mother)
- f (Father)
- c[0-9]*.[0-9]* (Children)
- mgm (Maternal grandmother)
- mgf (Maternal grandfather)
- pgm (Paternal grandmother)
- pgf (Paternal grandfather)
- s[0-9]* (Full siblings)
- mhs[0-9]* (Half-siblings - maternal side)
- phs[0-9]* (Half-siblings - paternal side)
- mau[0-9]* (Aunts/Uncles - maternal side)
- pau[0-9]* (Aunts/Uncles - paternal side). Defaults to NULL.

family_graphs   A tibble with columns pid and family_graph_col. See prepare_graph for con-
                        struction of the graphs. The family graphs Defaults to NULL.

h2_vec   A numeric vector representing the liability-scale heritabilities for all phenotypes.
                        All entries in h2_vec must be non-negative and at most 1.

genetic_corrmat

                        A numeric matrix holding the genetic correlations between the desired pheno-
                        types. All diagonal entries must be equal to one, while all off-diagonal entries
                        must be between -1 and 1. In addition, the matrix must be symmetric.

full_corrmat	A numeric matrix holding the full correlations between the desired phenotypes. All diagonal entries must be equal to one, while all off-diagonal entries must be between -1 and 1. In addition, the matrix must be symmetric.
phen_names	A character vector holding the phenotype names. These names will be used to create the row and column names for the covariance matrix. If it is not specified, the names will default to phenotype1, phenotype2, etc. Defaults to NULL.
pid	A string holding the name of the column in `family` and `threshs` that hold the personal identifier(s). Defaults to "PID".
fam_id	A string holding the name of the column in `family` that holds the family identifier. Defaults to "fam_ID".
role	A string holding the name of the column in `.tbl` that holds the role.Each role must be chosen from the following list of abbreviations

- g (Genetic component of full liability)
- o (Full liability)
- m (Mother)
- f (Father)
- c[0-9]*.[0-9]* (Children)
- mgm (Maternal grandmother)
- mgf (Maternal grandfather)
- pgm (Paternal grandmother)
- pgf (Paternal grandfather)
- s[0-9]* (Full siblings)
- mhs[0-9]* (Half-siblings - maternal side)
- phs[0-9]* (Half-siblings - paternal side)
- mau[0-9]* (Aunts/Uncles - maternal side)
- pau[0-9]* (Aunts/Uncles - paternal side). Defaults to "role".

family_graphs_col	
	Name of column with family graphs in family_graphs. Defaults to "fam_graph".
out	A character or numeric vector indicating whether the genetic component of the full liability, the full liability or both should be returned. If out = c(1) or out = c("genetic"), the genetic liability is estimated and returned. If out = c(2) or out = c("full"), the full liability is estimated and returned. If out = c(1,2) or out = c("genetic", "full"), both components are estimated and returned. Defaults to c(1).
tol	A number that is used as the convergence criterion for the Gibbs sampler. Equals the standard error of the mean. That is, a tolerance of 0.2 means that the standard error of the mean is below 0.2. Defaults to 0.01.

Details

This function can be used to estimate either the genetic component of the full liability, the full liability or both for a variable number of traits.

Value

If `family` and `threshs` are two matrices, lists or data frames that can be converted into tibbles, if `family` has two columns named like the strings represented in `pid` and `fam_id`, if `threshs` has a column named like the string given in `pid` as well as a column named `"lower"` and a column named `"upper"` and if the liability-scale heritabilities in `h2_vec`, `genetic_corrmat`, `full_corrmat`, `out` and `tol` are of the required form, then the function returns a tibble with at least six columns (depending on the length of `out`). The first two columns correspond to the columns `fam_id` and `pid` present in the tibble `family`. If `out` is equal to `c(1)` or `c("genetic")`, the third and fourth columns hold the estimated genetic liability as well as the corresponding standard error for the first phenotype, respectively. If `out` equals `c(2)` or `c("full")`, the third and fourth columns hold the estimated full liability as well as the corresponding standard error for the first phenotype, respectively. If `out` is equal to `c(1,2)` or `c("genetic","full")`, the third and fourth columns hold the estimated genetic liability as well as the corresponding standard error for the first phenotype, respectively, while the fifth and sixth columns hold the estimated full liability as well as the corresponding standard error for the first phenotype, respectively. estimate_liability_single

Estimating the genetic or full liability

Description

`estimate_liability_single` estimates the genetic component of the full liability and/or the full liability for a number of individuals based on their family history.

Usage

```
estimate_liability_single(
  .tbl = NULL,
  family_graphs = NULL,
  h2 = 0.5,
  pid = "PID",
  fam_id = "fam_ID",
  family_graphs_col = "fam_graph",
  role = NULL,
  out = c(1),
  tol = 0.01
)
```

Arguments

`.tbl`	A matrix, list or data frame that can be converted into a tibble. Must have at least five columns that hold the family identifier, the personal identifier, the role and the lower and upper thresholds. Note that the role must be one of the following abbreviations

- g (Genetic component of full liability)
- o (Full liability)
- m (Mother)
- f (Father)
- c[0-9]*.[0-9]* (Children)
- mgm (Maternal grandmother)
- mgf (Maternal grandfather)
- pgm (Paternal grandmother)
- pgf (Paternal grandfather)
- s[0-9]* (Full siblings)
- mhs[0-9]* (Half-siblings - maternal side)
- phs[0-9]* (Half-siblings - paternal side)
- mau[0-9]* (Aunts/Uncles - maternal side)
- pau[0-9]* (Aunts/Uncles - paternal side). Defaults to NULL.

`family_graphs`	A tibble with columns pid and family_graph_col. See prepare_graph for construction of the graphs. The family graphs Defaults to NULL.
`h2`	A number representing the heritability on liability scale for a single phenotype. Must be non-negative. Note that under the liability threshold model, the heritability must also be at most 1. Defaults to 0.5.
`pid`	A string holding the name of the column in `.tbl` (or `family` and `threshs`) that hold the personal identifier(s). Defaults to "PID".
`fam_id`	A string holding the name of the column in `.tbl` or `family` that holds the family identifier. Defaults to "fam_ID".
`family_graphs_col`	
	Name of column with family graphs in family_graphs. Defaults to "fam_graph".

role
: A string holding the name of the column in .tbl that holds the role. Each role must be chosen from the following list of abbreviations

- g (Genetic component of full liability)
- o (Full liability)
- m (Mother)
- f (Father)
- c[0-9]*.[0-9]* (Children)
- mgm (Maternal grandmother)
- mgf (Maternal grandfather)
- pgm (Paternal grandmother)
- pgf (Paternal grandfather)
- s[0-9]* (Full siblings)
- mhs[0-9]* (Half-siblings - maternal side)
- phs[0-9]* (Half-siblings - paternal side)
- mau[0-9]* (Aunts/Uncles - maternal side)
- pau[0-9]* (Aunts/Uncles - paternal side). Defaults to "role".

out
: A character or numeric vector indicating whether the genetic component of the full liability, the full liability or both should be returned. If out = c(1) or out = c("genetic"), the genetic liability is estimated and returned. If out = c(2) or out = c("full"), the full liability is estimated and returned. If out = c(1,2) or out = c("genetic", "full"), both components are estimated and returned. Defaults to c(1).

tol
: A number that is used as the convergence criterion for the Gibbs sampler. Equals the standard error of the mean. That is, a tolerance of 0.2 means that the standard error of the mean is below 0.2. Defaults to 0.01.

Details

This function can be used to estimate either the genetic component of the full liability, the full liability or both. It is possible to input either

Value

If family and threshs are two matrices, lists or data frames that can be converted into tibbles, if family has two columns named like the strings represented in pid and fam_id, if threshs has a column named like the string given in pid as well as a column named "lower" and a column named "upper" and if the liability-scale heritability h2, out, tol and always_add are of the required form, then the function returns a tibble with either four or six columns (depending on the length of out). The first two columns correspond to the columns fam_id and pid ' present in family. If out is equal to c(1) or c("genetic"), the third and fourth column hold the estimated genetic liability as well as the corresponding standard error, respectively. If out equals c(2) or c("full"), the third and fourth column hold the estimated full liability as well as the corresponding standard error, respectively. If out is equal to c(1,2) or c("genetic","full"), the third and fourth column hold the estimated genetic liability as well as the corresponding standard error, respectively, while the fifth and sixth column hold the estimated full liability as well as the corresponding standard error, respectively.

h2 = 0.5, n_sim=10, pop_prev = .05)
#
estimate_liability_single(.tbl = sims$thresholds,
h2 = 0.5, pid = "indiv_ID", fam_id = "fam_ID", role = "role",
out = c("genetic"), tol = 0.01)
```

---

get_all_combs   *construct all combinations of input vector*

Description

pastes together all combinations of input vector

Usage

```
get_all_combs(vec)
```

Arguments

vec   vector of strings

Value

A vector of strings is returned.

Examples

```
get_all_combs(letters[1:3])
```

get_kinship   *Construct kinship matrix from graph*

Description

construct the kinship matrix from a graph representation of a family, centered on an index person (proband).

Usage

```
get_kinship(fam_graph, h2, index_id = NA, add_ind = TRUE, fix_diag = TRUE)
```

Arguments

fam_graph	graph.
h2	heritability.
index_id	proband id. Only used in conjuction with add_ind = TRUE.
add_ind	add genetic liability to the kinship matrix. Defaults to true.
fix_diag	Whether to set diagonal to 1 for all entries except for the genetic liability.

Value

A kinship matrix.

Examples

```
fam <- data.frame(
i = c(1, 2, 3, 4),
f = c(3, 0, 4, 0),
m = c(2, 0, 0, 0)
)

thresholds <- data.frame(
  i = c(1, 2, 3, 4),
  lower = c(-Inf, -Inf, 0.8, 0.7),
  upper = c(0.8, 0.8, 0.8, 0.7)
)

graph <- prepare_graph(fam, icol = "i", fcol = "f", mcol = "m", thresholds = thresholds)

get_kinship(graph, h2 = 0.5, index_id = "1")
```

`get_relatedness` *Relatedness between a pair of family members*

Description

`get_relatedness` returns the relatedness times the liability-scale heritability for a pair of family members

Usage

```
get_relatedness(s1, s2, h2 = 0.5, from_covmat = FALSE)
```

Arguments

s1, s2   Strings representing the two family members. The strings must be chosen from the following list of strings:

- g (Genetic component of full liability)
- o (Full liability)
- m (Mother)
- f (Father)
- c[0-9]*.[0-9]* (Children)
- mgm (Maternal grandmother)
- mgf (Maternal grandfather)
- pgm (Paternal grandmother)
- pgf (Paternal grandfather)
- s[0-9]* (Full siblings)
- mhs[0-9]* (Half-siblings - maternal side)
- phs[0-9]* (Half-siblings - paternal side)
- mau[0-9]* (Aunts/Uncles - maternal side)
- pau[0-9]* (Aunts/Uncles - paternal side).

h2   A number representing the squared heritability on liability scale. Must be non-negative and at most 1. Defaults to 0.5

from_covmat   logical variable. Only used internally. allows for skip of negative check.

Details

This function can be used to get the percentage of shared DNA times the liability-scale heritability h^2 for two family members.

Value

If both s1 and s2 are strings chosen from the mentioned list of strings and h2 is a number satisfying $0 \leq h2 \leq 1$, then the output will be a number that equals the percentage of shared DNA between s1 and s2 times the squared heritability h2.

Note

If you are only interested in the percentage of shared DNA, set h2 = 1.

Examples

```
get_relatedness("g","o")
get_relatedness("g","f", h2 = 1)
get_relatedness("o","s", h2 = 0.3)

# This will result in errors:
try(get_relatedness("a","b"))
try(get_relatedness(m, mhs))
```

---

graph_based_covariance_construction
                        Constructing covariance matrix from local family graph

---

Description

Function that constructs the genetic covariance matrix given a graph around a proband and extracts the threshold information from the graph.

Usage

```
graph_based_covariance_construction(
  pid,
  cur_proband_id,
  cur_family_graph,
  h2,
  add_ind = TRUE
)
```

Arguments

pid	Name of column of personal ID
cur_proband_id	id of proband
cur_family_graph	
	local graph of current proband
h2	liability scale heritability
add_ind	whether to add genetic liability of the proband or not. Defaults to true.

Value

list with two elements. The first element is temp_tbl, which contains the id of the current proband, the family ID and the lower and upper thresholds. The second element, cov, is the covariance matrix of the local graph centered on the current proband.

Examples

```
fam <- data.frame(
  id = c("pid", "mom", "dad", "pgf"),
  dadcol = c("dad", 0, "pgf", 0),
  momcol = c("mom", 0, 0, 0))

thresholds <- data.frame(
  id = c("pid", "mom", "dad", "pgf"),
  lower = c(-Inf, -Inf, 0.8, 0.7),
  upper = c(0.8, 0.8, 0.8, 0.7))

graph <- prepare_graph(fam, icol = "id", fcol = "dadcol", mcol = "momcol", thresholds = thresholds)

graph_based_covariance_construction(pid = "id",
                                    cur_proband_id = "pid",
                                    cur_family_graph = graph,
                                    h2 = 0.5)
```

---

graph_based_covariance_construction_multi

Constructing covariance matrix from local family graph for multi trait analysis

---

Description

Function that constructs the genetic covariance matrix given a graph around a proband and extracts the threshold information from the graph.

Usage

```
graph_based_covariance_construction_multi(
  fam_id,
  pid,
  cur_proband_id,
  cur_family_graph,
  h2_vec,
  genetic_corrmat,
  phen_names,
  add_ind = TRUE
)
```

Arguments

fam_id	Name of column with the family ID
pid	Name of column of personal ID
cur_proband_id	id of proband

cur_family_graph
> local graph of current proband

h2_vec   vector of liability scale heritabilities

genetic_corrmat
> matrix with genetic correlations between considered phenotypes. Must have same order as h2_vec.

phen_names   Names of the phenotypes, as given in cur_family_graph.

add_ind   whether to add genetic liability of the proband or not. Defaults to true.

Value

list with three elements. The first element is temp_tbl, which contains the id of the current proband, the family ID and the lower and upper thresholds for all phenotypes. The second element, cov, is the covariance matrix of the local graph centred on the current proband. The third element is newOrder, which is the order of ids from pid and phen_names pasted together, such that order can be enforced elsewhere too.

Examples

```
fam <- data.frame(
fam = c(1, 1, 1,1),
id = c("pid", "mom", "dad", "pgf"),
dadcol = c("dad", 0, "pgf", 0),
momcol = c("mom", 0, 0, 0))

thresholds <- data.frame(
  id = c("pid", "mom", "dad", "pgf"),
  lower_1 = c(-Inf, -Inf, 0.8, 0.7),
  upper_1 = c(0.8, 0.8, 0.8, 0.7),
  lower_2 = c(-Inf, 0.3, -Inf, 0.2),
  upper_2 = c(0.3, 0.3, 0.3, 0.2))

graph <- prepare_graph(fam, icol = "id", fcol = "dadcol", mcol = "momcol", thresholds = thresholds)

ntrait <- 2
genetic_corrmat <- matrix(0.2, ncol = ntrait, nrow = ntrait)
diag(genetic_corrmat) <- 1
full_corrmat <- matrix(0.3, ncol = ntrait, nrow = ntrait)
diag(full_corrmat) <- 1
h2_vec <- rep(0.6, ntrait)

graph_based_covariance_construction_multi(fam_id = "fam",
                                          pid = "id",
                                          cur_proband_id = "pid",
                                          cur_family_graph = graph,
                                          h2_vec = h2_vec,
                                          genetic_corrmat = genetic_corrmat,
                                          phen_names = c("1", "2"))
```

prepare_graph	*Construct graph from register information*

Description

prepare_graph constructs a graph based on mother, father, and offspring links.

Usage

```
prepare_graph(
  .tbl,
  icol,
  fcol,
  mcol,
  thresholds,
  lower_col = "lower",
  upper_col = "upper",
  missingID_patterns = "^0$"
)
```

Arguments

.tbl	tibble with columns icol, fcol, mcol. Additional columns will be attributes in the constructed graph.
icol	column name of column with proband ids.
fcol	column name of column with father ids.
mcol	column name of column with mother ids.
thresholds	tibble with icol, lower_col and upper_col. Used to assign lower and upper thresholds to individuals in the graph as attributes.
lower_col	Column name of column with proband's lower threshold.
upper_col	Column name of column with proband's upper threshold.
missingID_patterns	
	string of missing values in the ID columns. Multiple values can be used, but must be separated by "|". Defaults to "^0$".

Value

An igraph object. A (directed) graph object based on the links provided in .tbl with the lower and upper thresholds stored as attributes.

Examples

```
fam <- data.frame(
  id = c("pid", "mom", "dad", "pgf"),
  dadcol = c("dad", 0, "pgf", 0),
  momcol = c("mom", 0, 0, 0))
```

```
thresholds <- data.frame(
  id = c("pid", "mom", "dad", "pgf"),
  lower = c(-Inf, -Inf, 0.8, 0.7),
  upper = c(0.8, 0.8, 0.8, 0.7))

prepare_graph(fam, icol = "id", fcol = "dadcol", mcol = "momcol", thresholds = thresholds)
```

---

prepare_LTFHPlus_input

Prepares input for estimate_liability

Description

Prepares input for estimate_liability

Usage

```
prepare_LTFHPlus_input(
  .tbl,
  CIP,
  age_col,
  aoo_col,
  CIP_merge_columns = c("sex", "birth_year", "age"),
  CIP_cip_col = "cip",
  status_col = "status",
  use_fixed_case_thr = FALSE,
  fam_id_col = "fam_id",
  personal_id_col = "pid",
  interpolation = NULL,
  bst.params = list(max_depth = 10, base_score = 0, nthread = 4, min_child_weight = 10),
  min_CIP_value = 1e-05,
  xgboost_itr = 50
)
```

Arguments

.tbl	contains family and personal ids and role with a family.
CIP	tibble with population representative cumulative incidence proportions. CIP values should be merged by CIP_columns.
age_col	name of column with age
aoo_col	name of column with age of onset
CIP_merge_columns	
	The columns the CIPs are subset by, e.g. CIPs by birth_year, sex.
CIP_cip_col	name of column with CIP values

status_col	Column that contains the status of each family member
use_fixed_case_thr	
	Should the threshold be fixed for cases? Can be used if CIPs are detailed, e.g. stratified by birth_year and sex.
fam_id_col	Column that contains the family ID
personal_id_col	
	Column that contains the personal ID
interpolation	type of interpolation, defaults to NULL.
bst.params	list of parameters to pass on to xgboost
min_CIP_value	minimum cip value to allow, too low values may lead to numerical instabilities.
xgboost_itr	Number of iterations to run xgboost for.

Value

tibble formatted for `estimate_liability`

Examples

```
tbl = data.frame(
  fam_id = c(1, 1, 1, 1),
  pid = c(1, 2, 3, 4),
  role = c("o", "m", "f", "pgf"),
  sex = c(1, 0, 1, 1),
  status = c(0, 0, 1, 1),
  age = c(22, 42, 48, 78),
  birth_year = 2023 - c(22, 42, 48, 78),
  aoo = c(NA, NA, 43, 45))

cip = data.frame(
  age = c(22, 42, 43, 45, 48, 78),
  birth_year = c(2001, 1981, 1975, 1945, 1975, 1945),
  sex = c(1, 0, 1, 1, 1, 1),
  cip = c(0.1, 0.2, 0.3, 0.3, 0.3, 0.4))

prepare_LTFHPlus_input(.tbl = tbl,
                       CIP = cip,
                       age_col = "age",
                       aoo_col = "aoo",
                       interpolation = NA)
```

---

rtmvnorm.gibbs   *Gibbs Sampler for the truncated multivariate normal distribution*

Description

`rtmvnorm.gibbs` implements Gibbs sampler for the truncated multivariate normal distribution with covariance matrix covmat.

Usage

```
rtmvnorm.gibbs(
  n_sim = 1e+05,
  covmat,
  lower = -Inf,
  upper,
  fixed = (lower == upper),
  out = c(1),
  burn_in = 1000
)
```

Arguments

n_sim	A positive number representing the number of draws from the Gibbs sampler after burn-in.. Defaults to `1e+05`.
covmat	A symmetric and numeric matrix representing the covariance matrix for the multivariate normal distribution.
lower	A number or numeric vector representing the lower cutoff point(s) for the truncated normal distribution. The length of lower must be 1 or equal to the dimension of the multivariable normal distribution. Defaults to `-Inf`.
upper	A number or numeric vector representing the upper cutoff point(s) for the truncated normal distribution. Must be greater or equal to lower. In addition the length of upper must be 1 or equal to the dimension of the multivariable normal distribution. Defaults to `Inf`.
fixed	A logical scalar or a logical vector indicating which variables to fix. If `fixed` is a vector, it must have the same length as lower and upper. Defaults to `TRUE` when `lower` is equal to `upper` and `FALSE` otherwise.
out	An integer or numeric vector indicating which variables should be returned from the Gibbs sampler. If `out = c(1)`, the first variable (usually the genetic component of the full liability of the first phenotype) is estimated and returned. If `out = c(2)`, the second variable (usually full liability) is estimated and returned. If `out = c(1,2)`, both the first and the second variable are estimated and returned. Defaults to `c(1)`.
burn_in	A number of iterations that count as burn in for the Gibbs sampler. Must be non-negative. Defaults to `1000`.

Details

Given a covariance matrix covmat and lower and upper cutoff points, the function `rtmvnorm.gibbs()` can be used to perform Gibbs sampler on a truncated multivariable normal distribution. It is possible to specify which variables to return from the Gibbs sampler, making it convenient to use when estimating only the full liability or the genetic component of the full liability.

Value

If covmat is a symmetric and numeric matrix, if `n_sim` and `burn_in` are positive/non-negative numbers, if out is a numeric vector and `lower`, `upper` and `fixed` are numbers or vectors of the

same length and the required format, `rtmvnorm.gibbs` returns the sampling values from the Gibbs sampler for all variables specified in out.

```
samp <- rtmvnorm.gibbs(10e3, covmat = matrix(c(1, 0.2, 0.2, 0.5), 2),
                       lower = c(-Inf, 0), upper = c(0, Inf), out = 1:2)
```

---

simulate_under_LTM   *Simulate under the liability threshold model.*

Description

`simulate_under_LTM` simulates families and thresholds under the liability threshold model for a given family structure and a variable number of phenotypes.Please note that it is not possible to simulate different family structures.

Usage

```
simulate_under_LTM(
  fam_vec = c("m", "f", "s1", "mgm", "mgf", "pgm", "pgf"),
  n_fam = NULL,
  add_ind = TRUE,
  h2 = 0.5,
  genetic_corrmat = NULL,
  full_corrmat = NULL,
  phen_names = NULL,
  n_sim = 1000,
  pop_prev = 0.1
)
```

Arguments

fam_vec   A vector of strings holding the different family members. All family members must be represented by strings from the following list:

- m (Mother)
- f (Father)
- c[0-9]*.[0-9]* (Children)

- mgm (Maternal grandmother)
- mgf (Maternal grandfather)
- pgm (Paternal grandmother)
- pgf (Paternal grandfather)
- s[0-9]* (Full siblings)
- mhs[0-9]* (Half-siblings - maternal side)
- phs[0-9]* (Half-siblings - paternal side)
- mau[0-9]* (Aunts/Uncles - maternal side)
- pau[0-9]* (Aunts/Uncles - paternal side). Defaults to c("m","f","s1","mgm","mgf","pgm","pgf

n_fam	A named vector holding the desired number of family members. See [setNames](). All names must be picked from the list mentioned above. Defaults to NULL.
add_ind	A logical scalar indicating whether the genetic component of the full liability as well as the full liability for the underlying target individual should be included in the covariance matrix. Defaults to TRUE.
h2	Either a number or a numeric vector holding the liability-scale heritability(ies) for one or more phenotypes. All entries in h2 must be non-negative. Note that under the liability threshold model, the heritabilities must also be at most 1. Defaults to 0.5.
genetic_corrmat	Either NULL or a numeric matrix holding the genetic correlations between the desired phenotypes. Must be specified, if length(h2)> 0, and will be ignored if h2 is a number. All diagonal entries in genetic_corrmat must be equal to one, while all off-diagonal entries must be between -1 and 1. In addition, the matrix must be symmetric. Defaults to NULL.
full_corrmat	Either NULL or a numeric matrix holding the full correlations between the desired phenotypes. Must be specified, if length(h2)> 0, and will be ignored if h2 is a number. All diagonal entries in full_corrmat must be equal to one, while all off-diagonal entries must be between -1 and 1. In addition, the matrix must be symmetric. Defaults to NULL.
phen_names	Either NULL or character vector holding the phenotype names. These names will be used to create the row and column names for the covariance matrix. Must be specified, if length(h2) > 0, and will be ignored if h2 is a number. If it is not specified, the names will default to phenotype1, phenotype2, etc. Defaults to NULL.
n_sim	A positive number representing the number of simulations. Defaults to 1000.
pop_prev	Either a number or a numeric vector holding the population prevalence(s), i.e. the overall prevalence(s) in the population. All entries in pop_prev must be positive and smaller than 1. Defaults to 0.1.

Details

This function can be used to simulate the case-control status, the current age and age-of-onset as well as the lower and upper thresholds for a variable number of phenotypes for all family members in each of the n_sim families. If h2 is a number, simulate_under_LTM simulates the case- control status, the current age and age-of-onset as well as thresholds for a single phenotype. However, if h2

is a numeric vector, if `genetic_corrmat` and `full_corrmat` are two symmetric correlation matrices, and if `phen_names` and `pop_prev` are to numeric vectors holding the phenotype names and the population prevalences, respectively, then `simulate_under_LTM` simulates the case-control status, the current age and age-of-onset as well as thresholds for two or more (correlated) phenotypes. The family members can be specified using one of two possible formats.

Value

If either `fam_vec` or `n_fam` is used as the argument, if it is of the required format, if the liability-scale heritability `h2` is a number satisfying $0 \leq h^2$, `n_sim` is a strictly positive number, and `pop_prev` is a positive number that is at most one, then the output will be a list containing two tibbles. The first tibble, `sim_obs`, holds the simulated liabilities, the disease status and the current age/age-of-onset for all family members in each of the `n_sim` families. The second tibble, `thresholds`, holds the family identifier, the personal identifier, the role (specified in fam_vec or n_fam) as well as the lower and upper thresholds for all individuals in all families. Note that this tibble has the format required in [estimate_liability](#). If either `fam_vec` or `n_fam` is used as the argument and if it is of the required format, if `genetic_corrmat` and `full_corrmat` are two numeric and symmetric matrices satisfying that all diagonal entries are one and that all off-diagonal entries are between -1 and 1, if the liability-scale heritabilities in `h2_vec` are numbers satisfying $0 \leq h_i^2$ for all $i \in \{1, ..., n_p heno\}$, `n_sim` is a strictly positive number, and `pop_prev` is a positive numeric vector such that all entries are at most one, then the output will be a list containing the following lists. The first outer list, which is named after the first phenotype in `phen_names`, holds the tibble `sim_obs`, which holds the simulated liabilities, the disease status and the current age/age-of-onset for all family members in each of the `n_sim` families for the first phenotype. As the first outer list, the second outer list, which is named after the second phenotype in `phen_names`, holds the tibble `sim_obs`, which holds the simulated liabilities, the disease status and the current age/age-of-onset for all family members in each of the `n_sim` families for the second phenotype. There is a list containing `sim_obs` for each phenotype in `phen_names`. The last list entry, `thresholds`, holds the family identifier, the personal identifier, the role (specified in fam_vec or n_fam) as well as the lower and upper thresholds for all individuals in all families and all phenotypes. Note that this tibble has the format required in [estimate_liability](#). Finally, note that if neither `fam_vec` nor `n_fam` are specified, the function returns the disease status, the current age/age-of-onset, the lower and upper thresholds, as well as the personal identifier for a single individual, namely the individual under consideration (called o). If both `fam_vec` and `n_fam` are defined, the user is asked to ' decide on which of the two vectors to use.

```

---

simulate_under_LTM_multi

Simulate under the liability threshold model (multiple phenotypes).

Description

`simulate_under_LTM_multi` simulates families and thresholds under the liability threshold model for a given family structure and multiple phenotypes. Please note that it is not possible to simulate different family structures.

Usage

```
simulate_under_LTM_multi(
  fam_vec = c("m", "f", "s1", "mgm", "mgf", "pgm", "pgf"),
  n_fam = NULL,
  add_ind = TRUE,
  genetic_corrmat = diag(3),
  full_corrmat = diag(3),
  h2_vec = rep(0.5, 3),
  phen_names = NULL,
  n_sim = 1000,
  pop_prev = rep(0.1, 3)
)
```

Arguments

fam_vec   A vector of strings holding the different family members. All family members
                 must be represented by strings from the following list:

- m (Mother)
- f (Father)
- c[0-9]*.[0-9]* (Children)
- mgm (Maternal grandmother)
- mgf (Maternal grandfather)
- pgm (Paternal grandmother)
- pgf (Paternal grandfather)
- s[0-9]* (Full siblings)
- mhs[0-9]* (Half-siblings - maternal side)

- phs[0-9]* (Half-siblings - paternal side)
- mau[0-9]* (Aunts/Uncles - maternal side)
- pau[0-9]* (Aunts/Uncles - paternal side). Defaults to c("m","f","s1","mgm","mgf","pgm","pgf

n_fam   A named vector holding the desired number of family members. See [setNames](). All names must be picked from the list mentioned above. Defaults to NULL.

add_ind   A logical scalar indicating whether the genetic component of the full liability as well as the full liability for the underlying target individual should be included in the covariance matrix. Defaults to TRUE.

genetic_corrmat
               A numeric matrix holding the genetic correlations between the desired phenotypes. All diagonal entries must be equal to one, while all off-diagonal entries must be between -1 and 1. In addition, the matrix must be symmetric. Defaults to diag(3).

full_corrmat   A numeric matrix holding the full correlations between the desired phenotypes. All diagonal entries must be equal to one, while all off-diagonal entries must be between -1 and 1. In addition, the matrix must be symmetric. Defaults to diag(3).

h2_vec   A numeric vector holding the liability-scale heritabilities for a number of phenotype. All entries must be non-negative. Note that under the liability threshold model, the heritabilities must also be at most 1. Defaults to rep(0.5,3).

phen_names   A character vector holding the phenotype names. These names will be used to create the row and column names for the covariance matrix. If it is not specified, the names will default to phenotype1, phenotype2, etc. Defaults to NULL.

n_sim   A positive number representing the number of simulations. Defaults to 1000.

pop_prev   A numeric vector holding the population prevalences, i.e. the overall prevalences in the population. All entries in pop_prev must be positive and smaller than 1. Defaults to rep(.1,3).

Value

If either fam_vec or n_fam is used as the argument and if it is of the required format, if genetic_corrmat and full_corrmat are two numeric and symmetric matrices satisfying that all diagonal entries are one and that all off-diagonal entries are between -1 and 1, if the liability-scale heritabilities in h2_vec are numbers satisfying $0 \leq h_i^2$ for all $i \in \{1,...,n_pheno\}$, n_sim is a strictly positive number, and pop_prev is a positive numeric vector such that all entries are at most one, then the output will be a list containing lists for each phenotype. The first outer list, which is named after the first phenotype in phen_names, holds the tibble sim_obs, which holds the simulated liabilities, the disease status and the current age/age-of-onset for all family members in each of the n_sim families for the first phenotype. As the first outer list, the second outer list, which is named after the second phenotype in phen_names, holds the tibble sim_obs, which holds the simulated liabilities, the disease status and the current age/age-of-onset for all family members in each of the n_sim families for the second phenotype. There is a list containing sim_obs for each phenotype in phen_names. The last list entry, thresholds, holds the family identifier, the personal identifier, the role (specified in fam_vec or n_fam) as well as the lower and upper thresholds for all individuals in all families and all phenotypes. Note that this tibble has the format required in [estimate_liability](). Finally, note that if neither fam_vec nor n_fam are specified, the function returns the disease status, the current age/age-of-onset, the lower and upper thresholds, as well as the personal identifier for a single

individual, namely the individual under consideration (called o). If both `fam_vec` and `n_fam` are defined, the user is asked to ' decide on which of the two vectors to use.

simulate_under_LTM_single

Simulate under the liability threshold model (single phenotype).

Description

`simulate_under_LTM_single` simulates families and thresholds under the liability threshold model for a given family structure and a single phenotype. Please note that it is not possible to simulate different family structures.

Usage

```
simulate_under_LTM_single(
  fam_vec = c("m", "f", "s1", "mgm", "mgf", "pgm", "pgf"),
  n_fam = NULL,
  add_ind = TRUE,
  h2 = 0.5,
  n_sim = 1000,
  pop_prev = 0.1
)
```

Arguments

fam_vec	A vector of strings holding the different family members. All family members must be represented by strings from the following list:

- m (Mother)
- f (Father)
- c[0-9]*.[0-9]* (Children)
- mgm (Maternal grandmother)
- mgf (Maternal grandfather)
- pgm (Paternal grandmother)
- pgf (Paternal grandfather)
- s[0-9]* (Full siblings)
- mhs[0-9]* (Half-siblings - maternal side)
- phs[0-9]* (Half-siblings - paternal side)
- mau[0-9]* (Aunts/Uncles - maternal side)
- pau[0-9]* (Aunts/Uncles - paternal side). Defaults to c("m","f","s1","mgm","mgf","pgm","pgf

n_fam	A named vector holding the desired number of family members. See [setNames](). All names must be picked from the list mentioned above. Defaults to NULL.
add_ind	A logical scalar indicating whether the genetic component of the full liability as well as the full liability for the underlying target individual should be included in the covariance matrix. Defaults to TRUE.
h2	A number representing the liability-scale heritability for a single phenotype. Must be non-negative. Note that under the liability threshold model, the heritability must also be at most 1. Defaults to 0.5.
n_sim	A positive number representing the number of simulations. Defaults to 1000.
pop_prev	A positive number representing the population prevalence, i.e. the overall prevalence in the population. Must be smaller than 1. Defaults to 0.1.

Value

If either fam_vec or n_fam is used as the argument, if it is of the required format, if the liability-scale heritability h2 is a number satisfying $0 \leq h^2$, n_sim is a strictly positive number, and pop_prev is a positive number that is at most one, then the output will be a list holding two tibbles. The first tibble, sim_obs, holds the simulated liabilities, the disease status and the current age/age-of-onset for all family members in each of the n_sim families. The second tibble, thresholds, holds the family identifier, the personal identifier, the role (specified in fam_vec or n_fam) as well as the lower and upper thresholds for all individuals in all families. Note that this tibble has the format required in [estimate_liability](). In addition, note that if neither fam_vec nor n_fam are specified, the function returns the disease status, the current age/age-of-onset, the lower and upper thresholds, as well as the personal identifier for a single individual, namely the individual under consideration (called o). If both fam_vec and n_fam are defined, the user is asked to ' decide on which of the two vectors to use.

truncated_normal_cdf   *CDF for truncated normal distribution.*

Description

`truncated_normal_cdf` computes the cumulative density function for a truncated normal distribution.

Usage

```
truncated_normal_cdf(
  liability,
  lower = stats::qnorm(0.05, lower.tail = FALSE),
  upper = Inf
)
```

Arguments

liability	A number representing the individual's true underlying liability.
lower	A number representing the lower cutoff point for the truncated normal distribution. Defaults to 1.645 (stats::qnorm(0.05, lower.tail = FALSE)).
upper	A number representing the upper cutoff point of the truncated normal distribution. Must be greater or equal to lower. Defaults to Inf.

Details

This function can be used to compute the value of the cumulative density function for a truncated normal distribution given an individual's true underlying liability.

Value

If liability is a number and the lower and upper cutoff points are numbers satisfying lower <= upper, then `truncated_normal_cdf` returns the probability that the liability will take on a value less than or equal to `liability`.

Examples

```
curve(sapply(liability, truncated_normal_cdf), from = qnorm(0.05, lower.tail = FALSE), to = 3.5,
 xname = "liability")
```
